

Chapter 5 Repetition (Loop)

Motivations

Suppose that you need to print a string (e.g., "Welcome to Java!") a hundred times. It would be tedious to have to write the following statement a hundred times:

System.out.println("Welcome to Java!");

So, how do you solve this problem?

Opening Problem

Problem:

```
System.out.println("Welcome to Java!");
         System.out.println("Welcome to Java!");
100
times
         System.out.println("Welcome to Java!");
         System.out.println("Welcome to Java!");
         System.out.println("Welcome to Java!");
```

Introducing while Loops

```
int count = 0;
while (count < 100) {
   System.out.println("Welcome to Java");
   count++;
}</pre>
```

- The Essentials of Repetition
- Counter-Controlled Repetition
- The for Repetition Structure
- The while Repetition Structure
- The do...while Repetition Structure
- Nested loops
- The keyword break and continue

while Loop Flow Chart

```
initial-action
while (loop-continuation-condition) {
 // loop-body;
 Statement(s);
 action-after-each-iteration
                    loop-
                                 false
                 continuation-
                  condition?
                  true
                 Statement(s)
                  (loop body)
```

```
int count = 0;
while (count < 100) {
 System.out.println("Welcome to Java!");
 count++;
               count = 0;
                                false
             (count < 100)?
                true
System.out.println("Welcome to Java!");
count++:
```

Trace while Loop

```
int count = 0;
while (count < 2) {
   System.out.println("Welcome to Java!");
   count++;
}</pre>
```

```
int count = 0;
while (count < 2) {
    System.out.println("Welcome to Java!");
    count++;
}</pre>
```

```
int count = 0;
while (count < 2) {
    System.out.println("Welcome to Java!");
    count++;
}</pre>
```

```
int count = 0;
while (count < 2) {
   System.out.println("Welcome to Java!"
   count++;
}</pre>
```

Increase count by 1 count is 1 now

```
int count = 0;
while (count < 2) {
    System.out.println("Welcome to Java!");
    count++;
}</pre>
```

```
int count = 0;
while (count < 2) {
    System.out.println("Welcome to Java!");
    count++;
}</pre>
```

Print Welcome to Java

```
int count = 0;
while (count < 2) {
   System.out.println("Welcome to Java!"
   count++;
}</pre>
```

Increase count by 1 count is 2 now

```
int count = 0;
while (count < 2) {
    System.out.println("Welcome to Java!");
    count++;
}</pre>
```

Trace while Loop

```
int count = 0;
while (count < 2) {
   System.out.println("Welcome to Java!");
   count++;
}</pre>
```

The loop exits. Execute the next statement after the loop.

Problem: Repeat Addition Until Correct

Recall that Listing 3.1 AdditionQuiz.java gives a program that prompts the user to enter an answer for a question on addition of two single digits. Using a loop, you can now rewrite the program to let the user enter a new answer until it is correct.

Problem: Guessing Numbers

Write a program that randomly generates an integer between <u>0</u> and <u>100</u>, inclusive. The program prompts the user to enter a number continuously until the number matches the randomly generated number. For each user input, the program tells the user whether the input is too low or too high, so the user can choose the next input intelligently. Here is a sample run:

Problem: An Advanced Math Learning Tool

The Math subtraction learning tool program generates just one question for each run. You can use a loop to generate questions repeatedly. This example gives a program that generates five questions and reports the number of the correct answers after a student answers all five questions.

Ending a Loop with a Sentinel Value

Often the number of times a loop is executed is not predetermined. You may use an input value to signify the end of the loop. Such a value is known as a *sentinel value*.

Write a program that reads and calculates the sum of an unspecified number of integers. The input 0 signifies the end of the input.

SentinelValue

Caution

Don't use floating-point values for equality checking in a loop control. Since floating-point values are approximations for some values, using them could result in imprecise counter values and inaccurate results. Consider the following code for computing 1 + 0.9 + 0.8 + ... + 0.1:

```
double item = 1; double sum = 0;
while (item != 0) { // No guarantee item will be 0
   sum += item;
   item -= 0.1;
}
System.out.println(sum);
```

```

                                               (loop body)
                                                 loop-
                                       true
                                              continuation-
                                               condition?
do {
  // Loop body;
                                                   false
  Statement(s);
  while (loop-continuation-condition);
```

for Loops

```
for (initial-action; loop-
                                                     int i;
   continuation-condition; action-
                                                     for (i = 0; i < 100; i++)
   after-each-iteration) {
                                                       System.out.println(
  // loop body;
                                                         "Welcome to Java!");
  Statement(s);
                       initial-action
                          loop-
                                   false
                                                                    false
                       continuation-
                                                       (i < 100)?
                        condition?
                        true
                                                         true
                                                  System.out.println(
                       Statement(s)
                                                     "Welcome to Java");
                        (loop body)
                   action-after-each-iteration
```

Trace for Loop

```
int i;

for (i = 0; i < 2; i++) {

System.out.println("Welcome to Java!");
}
```

```
int i; 
 for (i = 0; i < 2; i++) { System.out.println("Welcome to Java!"); }
```

```
int i; (i < 2) \text{ is true since i is 0} for (i = 0; i < 2; i++) { System.out.println("Welcome to Java!"); }
```

```
int i; for (i=0;\,i<2;\,i++) { System.out.println("Welcome to Java!"); }
```

```
int i; i \text{ now is 1} for (i = 0; i < 2; i++) { System.out.println("Welcome to Java!"); }
```

```
int i; (i < 2) \text{ is still true} \text{since i is 1} for (i = 0; \underbrace{i < 2; i++}) { System.out.println("Welcome to Java!"); }
```

```
int i; for (i = 0; i < 2; i++) { System.out.println("Welcome to Java!"); }
```

```
int i; i now is 2 for (i = 0; i < 2; i++) { System.out.println("Welcome to Java!"); }
```

```
int i; (i < 2) \text{ is false} \text{since i is 2} \text{for } (i = 0; \underbrace{i < 2; i++}) \{ \text{System.out.println("Welcome to Java!");} \}
```

```
int i;
for (i = 0; i < 2; i++) {
   System.out.println("Welcome to Java')
}</pre>
```

Exit the loop. Execute the next statement after the loop

Note

The <u>initial-action</u> in a <u>for</u> loop can be a list of zero or more comma-separated expressions. The <u>action-after-each-iteration</u> in a <u>for</u> loop can be a list of zero or more comma-separated statements. Therefore, the following two <u>for</u> loops are correct. They are rarely used in practice, however.

```
for (int i = 1; i < 100; System.out.println(i++));
```

```
for (int i = 0, j = 0; (i + j < 10); i++, j++) {  // Do something }
```

Note

If the <u>loop-continuation-condition</u> in a <u>for</u> loop is omitted, it is implicitly true. Thus the statement given below in (a), which is an infinite loop, is correct. Nevertheless, it is better to use the equivalent loop in (b) to avoid confusion:

```
for (;;) {
// Do something
}

Equivalent
// Do something
}

(a)

(b)
```

Caution

Adding a semicolon at the end of the <u>for</u> clause before the loop body is a common mistake, as shown below:

```
Logic
                                Error
for (int i=0; i<10; i++);
  System.out.println("i is " + i);
```

Caution, cont.

```
Similarly, the following loop is also wrong: int i=0; while (i < 10); Logic Error {
    System.out.println("i is " + i); i++; }
```

In the case of the <u>do</u> loop, the following semicolon is needed to end the loop.

Which Loop to Use?

The three forms of loop statements, while, do-while, and for, are expressively equivalent; that is, you can write a loop in any of these three forms. For example, a while loop in (a) in the following figure can always be converted into the following for loop in (b):

A for loop in (a) in the following figure can generally be converted into the following while loop in (b) except in certain special cases.

Recommendations

Use the one that is most intuitive and comfortable for you. In general,

- A for loop may be used if the number of repetitions is known, as, for example, when you need to print a message 100 times.
- A while loop may be used if the number of repetitions is not known, as in the case of reading the numbers until the input is 0.
- A do-while loop can be used to replace a while loop if the loop body has to be executed before testing the continuation condition.

Nested Loops

Problem: Write a program that uses nested for loops to print a multiplication table.

MultiplicationTable

Minimizing Numerical Errors

Numeric errors involving floating-point numbers are inevitable.

Here is an example that sums a series that starts with 0.01 and ends with 1.0. The numbers in the series will increment by 0.01, as follows: 0.01 + 0.02 + 0.03 and so on.

TestSum

Problem:

Finding the Greatest Common Divisor

Problem: Write a program that prompts the user to enter two positive integers and finds their greatest common divisor.

Solution: Suppose you enter two integers 4 and 2, their greatest common divisor is 2. Suppose you enter two integers 16 and 24, their greatest common divisor is 8. So, how do you find the greatest common divisor? Let the two input integers be n1 and n2. You know number 1 is a common divisor, but it may not be the greatest commons divisor. So you can check whether k (for k = 2, 3, 4, and so on) is a common divisor for n1 and n2, until k is greater than n1 or n2.

GreatestCommonDivisor

Problem: Predicting the Future Tuition

Problem: Suppose that the tuition for a university is \$10,000 this year and tuition increases 7% every year. In how many years will the tuition be doubled?

Future Tuition

Problem: Predicating the Future Tuition

```
double tuition = 10000; int year = 0 // Year 0
tuition = tuition * 1.07; year++; // Year 1
tuition = tuition * 1.07; year++; // Year 2
tuition = tuition * 1.07; year++; // Year 3
```

Case Study: Converting Decimals to Hexadecimals

Hexadecimals are often used in computer systems programming (see Appendix F for an introduction to number systems). How do you convert a decimal number to a hexadecimal number? To convert a decimal number d to a hexadecimal number is to find the hexadecimal digits h_n , h_{n-1} , h_{n-2} , ..., h_2 , h_1 , and h_0 such that

$$d = h_n \times 16^n + h_{n-1} \times 16^{n-1} + h_{n-2} \times 16^{n-2} + \dots + h_2 \times 16^2 + h_1 \times 16^1 + h_0 \times 16^0$$

These hexadecimal digits can be found by successively dividing d by 16 until the quotient is 0. The remainders are h_0 , h_1 , h_2 , ..., h_{n-2} , h_{n-1} , and h_n .

Using break and continue

Examples for using the break and continue keywords:

TestBreak.java

TestBreak

TestContinue.java

TestContinue

break

```
public class TestBreak {
  public static void main(String[] args) {
    int sum = 0;
    int number = 0;
    while (number < 10) {</pre>
      number++;
      sum += number;
      if (sum >= 20)
       break;
    System.out.println("The number is " + number);
    System.out.println("The sum is " + sum);
```

continue

```
public class TestContinue {
  public static void main(String[] args) {
    int sum = 0;
    int number = 0;
    while (number < 10) {</pre>
      number++;
      if (number == 6 \mid \mid number == 7)
      __continue;
     sum += number;
    System.out.println("The sum is " + sum);
```

Guessing Number Problem Revisited

Here is a program for guessing a number. You can rewrite it using a <u>break</u> statement.

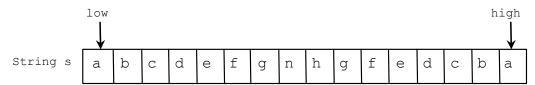

Guess Number Using Break

Problem: Checking Palindrome

A string is a palindrome if it reads the same forward and backward. The words "mom," "dad," and "noon," for instance, are all palindromes.

The problem is to write a program that prompts the user to enter a string and reports whether the string is a palindrome. One solution is to check whether the first character in the string is the same as the last character. If so, check whether the second character is the same as the second-to-last character. This process continues until a mismatch is found or all the characters in the string are checked, except for the middle character if the string has an odd number of characters.

Problem: Displaying Prime Numbers

Problem: Write a program that displays the first 50 prime numbers in five lines, each of which contains 10 numbers. An integer greater than 1 is *prime* if its only positive divisor is 1 or itself. For example, 2, 3, 5, and 7 are prime numbers, but 4, 6, 8, and 9 are not.

Solution: The problem can be broken into the following tasks:

- •For number = 2, 3, 4, 5, 6, ..., test whether the number is prime.
- •Determine whether a given number is prime.
- •Count the prime numbers.
- •Print each prime number, and print 10 numbers per line.
